

IgG₃ as a Biomarker for Distinguishing Recent from Established HIV-1 Infection

Kelly A. Curtis, M. Susan Kennedy, Kevin Delaney, Man Charurat, and S. Michele Owen

Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA

Serological Assays for Determining Recent HIV Infection

▣ Advantages:

- Obvious evolution of antibody response to HIV- antibody quantity and avidity gradually increase as disease progresses.
- Antibody in plasma samples is relatively stable.

▣ Challenges:

- Identify most reliable marker/markers for differentiating early from late infection.
- Reduce number of false reagents due to variations in the antibody response, drug therapy, advanced disease state, etc.

▣ Approaches:

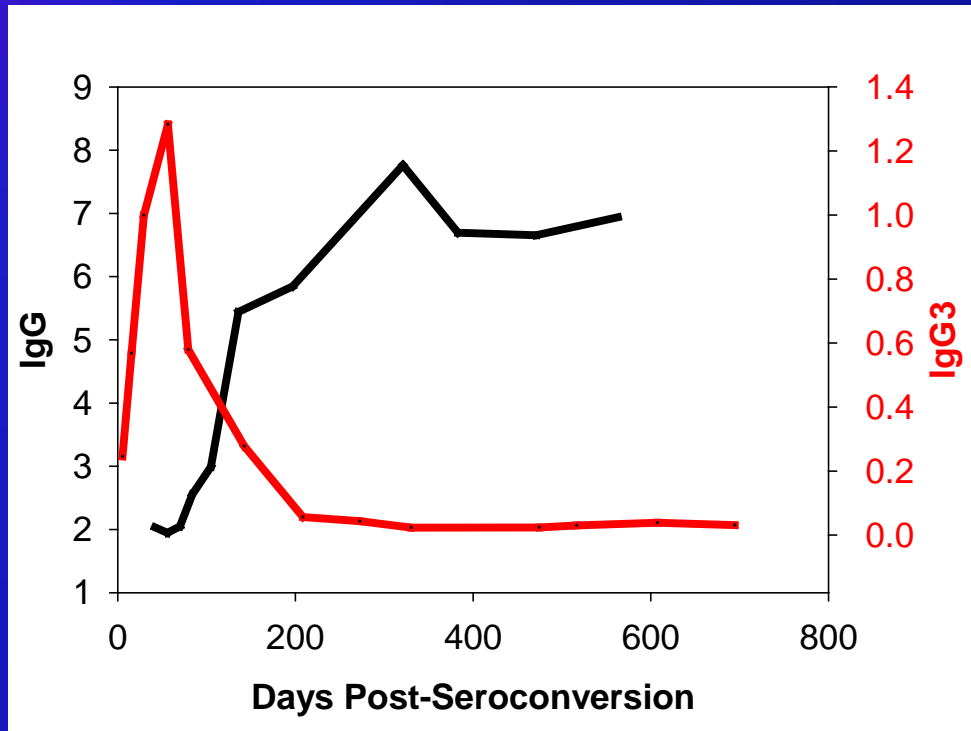

- Antibody titer
- Avidity Index
- Antibody subclass

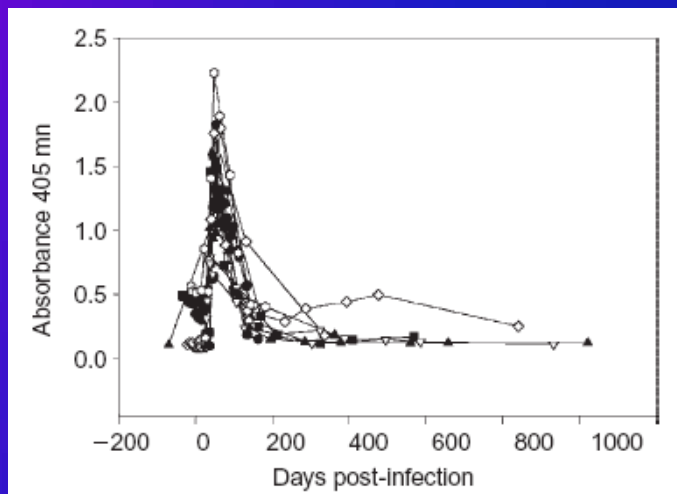

IgG Subclass

- ▣ IgG₁:
 - Predominant subclass directed against HIV (major component of total IgG).
 - Increases steadily post-infection.
- ▣ IgG₂ and IgG₄:
 - Not frequently found.
- ▣ IgG₃:
 - Produced early post-infection.
 - Decreases after initial peak in reactivity.

Temporal Relationship Between IgG₃ and Total IgG (IgG₁)

IgG₃ as a Biomarker for Recent Infection

- Developed an IgG₃-specific p24 ELISA
- Detectable peak of IgG₃ reactivity was observed in 17 seroconversion panels
- Window of detection ranged from 34 to 120 days post-infection

Wilson et al., AIDS, 2004

Luminex Assay (Bio-Plex System)

- ▣ Sensitive, quantitative detection of antibody.
- ▣ Detection of multiple analytes in a single well.
- ▣ Assay can be customized to detect up to 100 different analytes (100 different microsphere sets).
- ▣ Uses extremely small sample volume (1μl/well).

Assay Procedure

Beads conjugated
to specific antigen

p24
p66
p31
gp120
gp160
gp41

+

Diluted
patient
plasma

+

PE-conjugated
anti-human IgG₃

Bio-Plex Suspension Array System

Microspheres are aligned in single file and passed through 2 lasers

1st laser excites molecular tags- Data output as mean fluorescent intensity (MFI)

2nd laser excites microsphere and identifies dye signature

Samples Tested

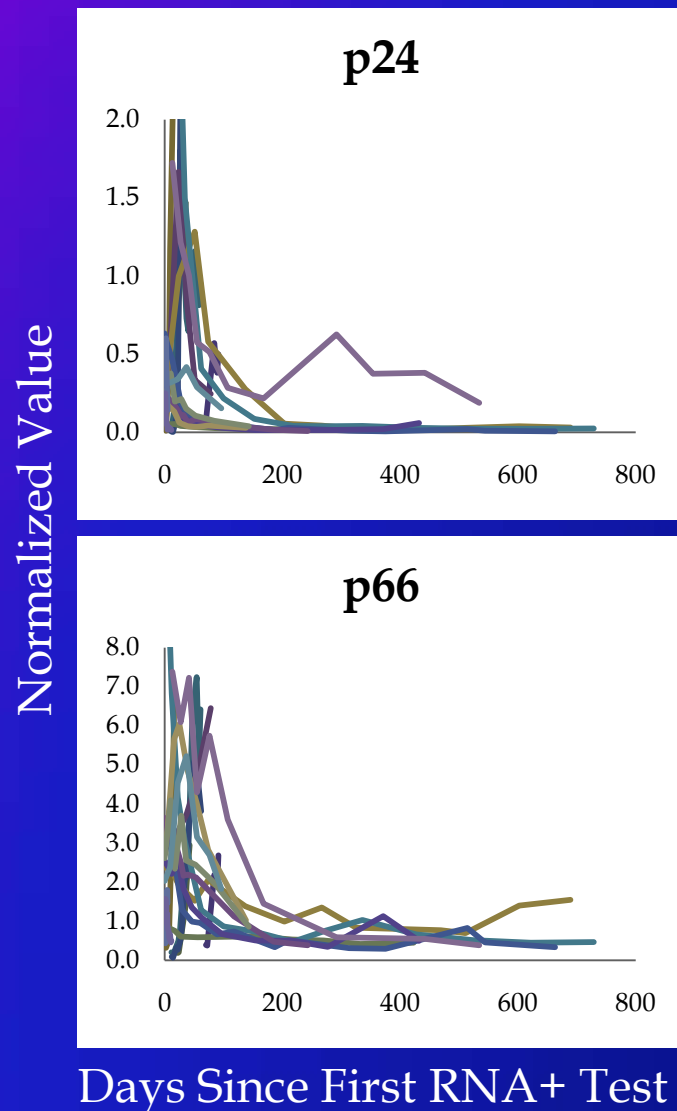

- ▣ Seroconversion Panels/Longitudinal Specimens:
 - Total- 1377 specimens/ 382 subjects
 - ▣ Includes subtypes- B, B', E, A, and G
 - ▣ Timing of IgG₃ detection- 23 panels (148 specimens)
 - ▣ Peak IgG₃ detection- 18 panels (177 specimens)
 - ▣ Longitudinal detection- 1200 specimens/ 332 subjects
- ▣ ART:
 - Total- 557 specimens/ 104 subjects
- ▣ AIDS and LT Non-Progressors:
 - Total- 350 specimens/ 138 subjects

IgG₃ Detection

Median time to detection=
19 days for p24 and 26 days for p66

Seroconversion Panels

- ▣ Evaluated 18 seroconversion panels
- ▣ Peak of IgG₃ reactivity was observed shortly after initial detection
 - Median= 26 days (p24)
 - Median= 37 days (p66)
(7 and 11 days post initial detection)

Longitudinal Specimens

1200 samples from 332 subjects

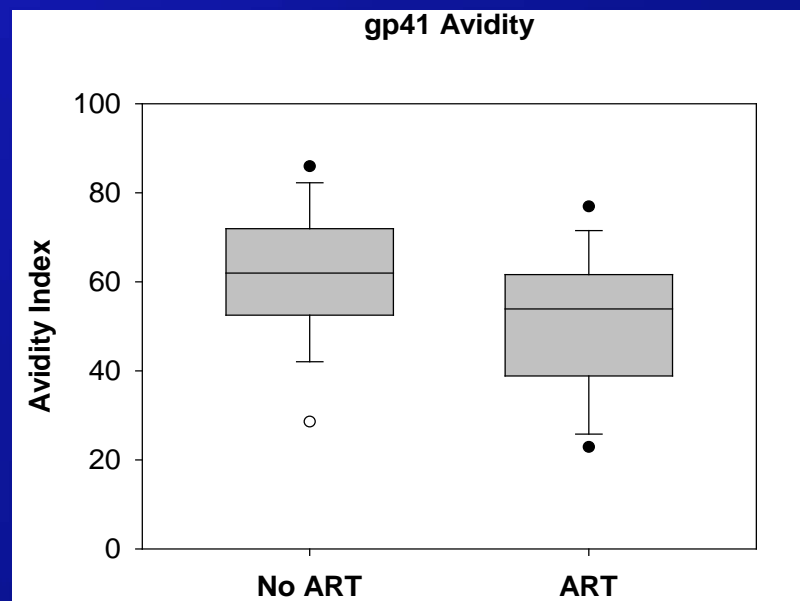

Days Since Seroconversion

- ❖ **p24**- Reactivity drops drastically after 50 days post-seroconversion.
- ❖ **p66**- Reactivity begins to decline after 100 days.

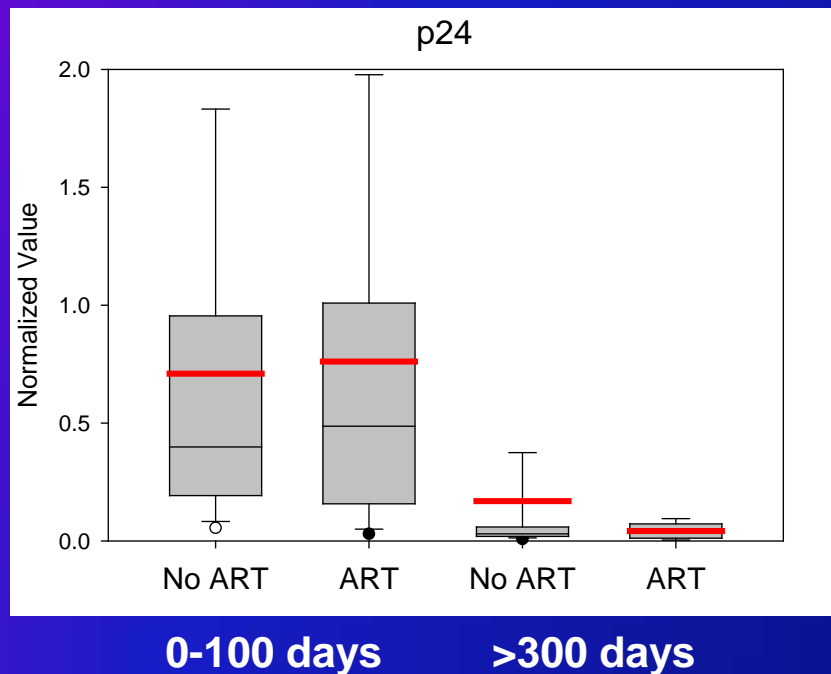

Effects of ART on Serological Assays

Total IgG response to gp41 in individuals infected >365 days

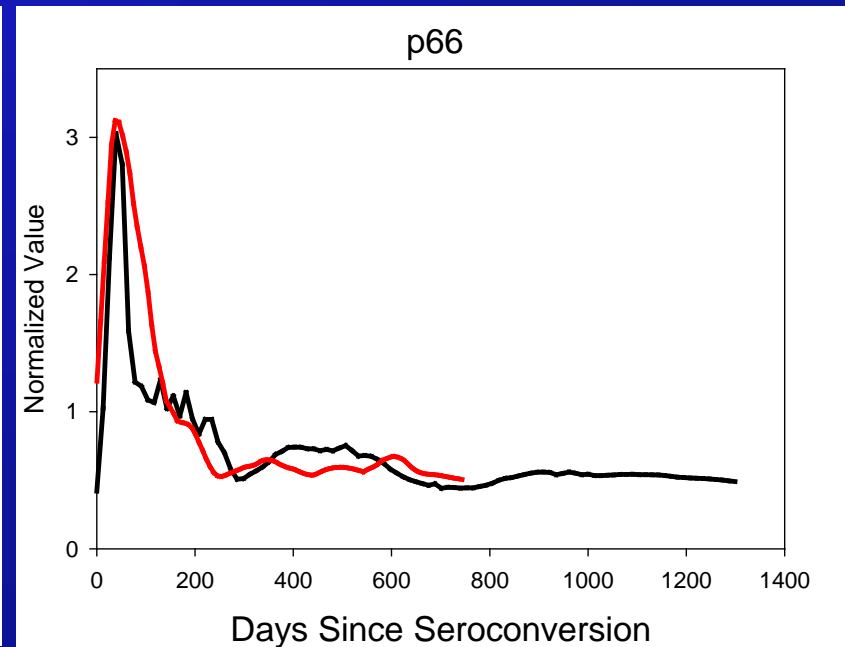

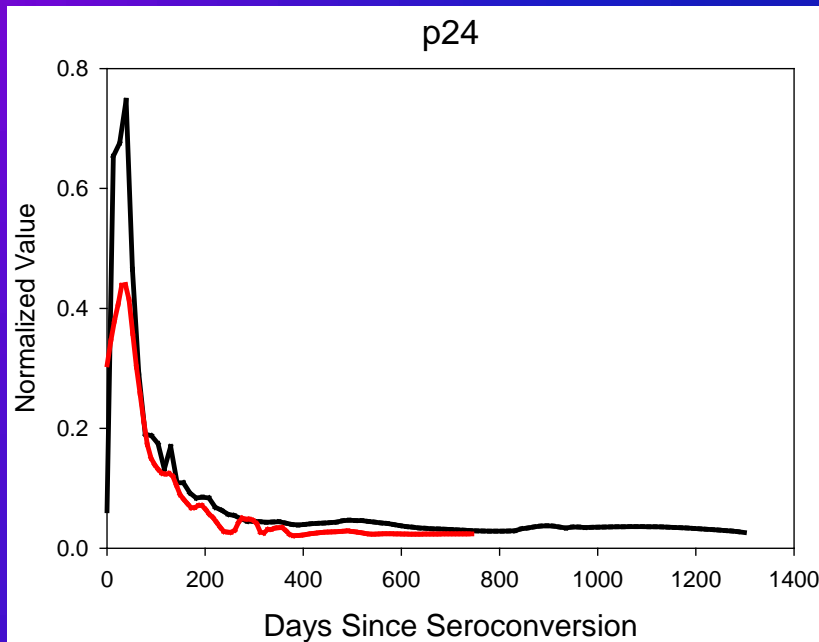

*Reduction in antibody levels and avidity, especially if ART is initiated early post infection

ART and the IgG₃ Response

*Lower likelihood of false recent caused by ART

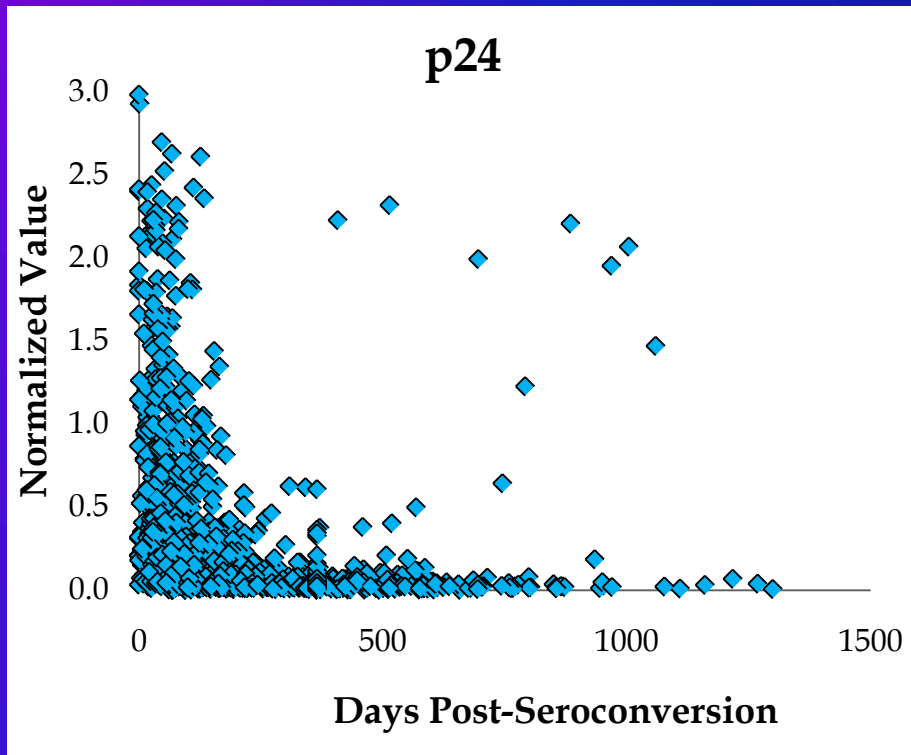

HIV-1 Subtype

— Subtype B (645 specimens/143 subjects)
— Subtype A/G (131 specimens/13 subjects)

*Evaluation of multiple subtypes is needed

Summary

1200 samples from 332 subjects

- IgG₃ directed against p24 and p66 appears to be a good indicator for early infection.
- As a single determinant of recent infection, there will still be some misclassification due to individuals that do not follow the rule. (*Similar outliers were observed with AIDS/LT samples)

Algorithms for Determining Recent HIV Infection

- ▣ Increasing number of studies evaluating algorithms of different tests for estimating HIV incidence.
- ▣ Bio-Plex assay incorporates multiple analyses in 1 test.
 - Currently developing an assay that determines recent infection based on 8 different antibody measures (poster)
 - ▣ Antibody quantity and avidity for total IgG
 - Evaluating feasibility of incorporating IgG₃ subclass into multiplexed assay
 - **Determining recent infection based on an antibody profile as opposed to a single measure**

Identification of Recent Infection Based on Antibody Profile

■ Known recent
■ Known LT

*Each bar represents 1 individual

Next Steps

- ▣ Statistics, statistics, statistics.
 - Results from ~2500 specimens.
 - Assay cutoffs.
 - Window period of detection.
 - Assay validation with additional samples- LT samples are underrepresented.
- ▣ Feasibility of multiplexing IgG3 with total IgG measures.
- ▣ Feasibility of IgG₃ as a stand-alone assay- ratio of IgG₃ to total IgG
- ▣ Evaluation of additional analytes.
